C++ Templates: The Complete Guide (2nd)
D. Vandevoorde, N. M. Josuttis, D. Gregor, 2017

Function Template

Template

A **template** is a mechanism for generic programming to provide a *"schema"* (or *placeholders*) to represent the structure of an entity

In C++, *templates* are a compile-time functionality to represent:

- A family of **functions**
- A family of **classes**
- A family of **variables** C++14

The problem: We want to define a function to handle different types

```cpp
int add(int a, int b) {
    return a + b;
}

float add(float a, float b) { // overloading
    return a + b;
}

char  add(char a, char b)     { ... } // overloading
ClassX add(ClassX a, ClassX b) { ... } // overloading
```

- Redundant code!!
- How many functions we have to write!?
- If the user introduces a new type we have to write another function!!

Function Template

A **function template** is a function schema that operates with *generic* types
(independent of any particular type) or concrete values

A function template works with multiple types without repeating the entire code for
each of them

```
template<typename T> // or template<class T>
T add(T a, T b) {
    return a + b;
}

int   c1 = add(3, 4);       // c1 = 7
float c2 = add(3.0f, 4.0f); // c2 = 7.0f
```

Templates: Benefits and Drawbacks

Benefits

- **Generic Programming**: Less code and reusable. Reduce *redundancy*, better *maintainability* and *flexibility*

- **Performance**. Computation can be done/optimized at compile-time → *faster*

Drawbacks

- **Readability**. "With respect to C++, the syntax and idioms of templates are *esoteric* compared to conventional C++ programming, and templates can be very difficult to understand" [wikipedia] → hard to read, cryptic error messages

- **Compile Time/Binary Size**. Templates are implicitly instantiated for every distinct parameters

Template Instantiation

Template Instantiation

The **template instantiation** is the substitution of template parameters with concrete values or types

The compiler *automatically* generates a **function implementation** for each template instantiation

```cpp
template<typename T>
T add(T a, T b) {
    return a + b;
}
add(3, 4);      // generates: int   add(int, int)
add(3.0f, 4.0f); // generates: float add(float, float)
add(2, 6);      // already generated
// other instances are not generated
// e.g. char add(char,char)
```

Implicit and Explicit Template Instantiation

Implicit Template Instantiation

Implicit template instantiation occurs when the compiler generates code depending on the deduced argument types or the explicit template arguments, and such entity is used in the code

Explicit Template Instantiation

Explicit template instantiation occurs when the compiler generates code depending only on the explicit template arguments specified in the declaration. Useful when dealing with multiple translation units to reduce the binary size

```cpp
template<typename T>
void f(T a) {}

f(3);                 // generates: void f(int) → implicit
f<short>(3.0);        // generates: void f(short) → explicit
template f<int>(int); // generates: void f(int) → explicit
```

Template Parameters

Template Parameters

Template Parameters are the names following the template keyword

```
template<typename T>
void f() {}

f<int>();
```

typename T is the **template parameter**

int is the **template argument**

A **template parameter** can be a *generic type*, i.e. typename , as well as a
non-type template parameters (NTTP), e.g. int , enum , etc.

The **template argument** of a *generic type* is a builtin or user-declared type, while a
concrete value for a *non-type template parameter*

int parameter

```cpp
template<int A, int B>
int add_int() {
    return A + B; // sum is computed at compile-time
}                 // e.g. add_int<3, 4>();
```

enum parameter

```cpp
enum class Enum { Left, Right };

template<Enum Z>
int add_enum(int a, int b) {
    return (Z == Enum::Left) ? a + b : a;
}        // e.g. add_enum<Enum::Left>(3, 4);
```

- **Ceiling division**

```
template<int DIV, typename T>
T ceil_div(T value) {
    return (value + DIV - 1) / DIV;
}
// e.g. ceil_div<5>(11); // returns 3
```

- **Rounded division**

```
template<int DIV, typename T>
T round_div(T value) {
    return (value + DIV / 2) / DIV;
}
// e.g. round_div<5>(11); // returns 2 (2.2)
```

Since DIV is known at compile-time, the compiler can heavily optimize the division
(almost for every numbers, not just for power of two)

C++11 **Template parameters can have default values**
(only at the end of the parameter list)

```cpp
// template<int A = 3, int B>   // compile error
template<int A = 3>
int print1() {
    cout << A;
}

print1<2>(); // print 2
print1<>(); // print 3 (default)
print1(); // print 3 (default)
```

Template parameters may have no name

```
void f() {}

template<typename = void>
void g() {}

int main() {
    g();  // generated
}
```

f() is always generated in the final code

g() is generated in the final code only if it is called

C++11 **Unlike function parameters, template parameters can be initialized by previous values**

```cpp
template<int A, int B = A + 3>
void f() {
    cout << B;
}

template<typename T, int S = sizeof(T)>
void g(T) {
    cout << S;
}

f<3>();  // B is 6
g(3);    // S is 4
```

Function Template Overloading

Template Functions can be *overloaded*

```
template<typename T>
T add(T a, T b) {
    return a + b;
} // e.g add(3, 4);

template<typename T>
T add(T a, T b, T c) { // different number of parameters
    return a + b + c;
} // e.g add(3, 4, 5);
```

Also templates themselves can be *overloaded*

```
template<int C, typename T>
T add(T a, T b) {       // it is not in conflict with
    return a + b + C;   // T add(T a, T b)
}                       // "C" is part of the signature
```

Template Specialization

Template specialization refers to the concrete implementation for a specific combination of template parameters

The problem:

```
template<typename T>
bool compare(T a, T b) {
    return a < b;
}
```

The direct comparison between two floating-point values is dangerous due to rounding errors

Solution: Template specialization

```
template<>
bool compare<float>(float a, float b) {
    return ...   // a better floating point implementation
}
```

Full Specialization: *Function* templates can be specialized only if **ALL** template arguments are specialized

Template Variable

Template Variable

C++14 allows variables with templates

A template variable can be considered a special case of a template class

```cpp
template<typename T>
constexpr T pi{ 3.1415926535897932385 }; // variable template

template<typename T>
T circular_area(T r) {
    return pi<T> * r * r; // pi<T> is a variable template instantiation
}

circular_area(3.3f); // float
circular_area(3.3);  // double
// circular_area(3); // compile error, narrowing conversion with "pi"
```

Template Parameter Types

Template Parameter Types

Template parameters can be:

- *integral type*
- `enum`, `enum class`
- *floating-point type* C++20
- `auto` placeholder C++17
- *class literals* and *concepts* C++20
- *generic type* `typename`

and rarely:

- *function*
- *reference/pointer* to global `static` function or object
- *pointer to member type*
- `nullptr_t` C++14

Generic Type Notes

Pass multiple values and floating-point types

```cpp
// template<float V>  // compiler error
// void print() {     // not valid before C++20

template<typename T>
void print() {
    cout << T::x << ", " << T::y;
}

struct Multi {
    static const    int   x = 1;
    static constexpr float y = 2.0f; // preferred
};

print<Multi>(); // print 2.0, 3.0
```

`auto` Placeholder

C++17 introduces automatic deduction of *non-type* template parameters with the `auto` keyword

```cpp
template<int X, int Y>
void f() {}

template<typename T1, T1 X, typename T2, T2 Y>
void g1() {} // before C++17

template<auto X, auto Y>
void g2() {}

f<2u, 2u>();           // X: int, Y: int
g1<int, 2, char, 'a'>(); // X: int, Y: char
g2<2, 'a'>();          // X: int, Y: char
```

Class Template Parameter Type

C++20 A *non-type template parameter* of a **class literal type**:

- A *class literal* is a class that can be assigned to `constexpr` variable
- All *base* classes and *non-static data members* are `public` and `non-mutable`
- All *base* classes and *non-static data members* have the same properties

```cpp
#include <array>
struct A {
    int x;
    constexpr A(int x1) : x{x1} {}
};
template<A a>
void f() { std::cout << a.x; }

template<std::array array>
void g() { std::cout << array[2]; }

f<A{5}>();            // print '5'
g<std::array{1,2,3}>(); // print '3'
```

Array and pointer

```cpp
template<int* ptr>     // pointer
void g() {
    cout << ptr[0];
}

template<int (&array)[3]> // reference
void f() {
    cout << array[0];
}

int array[] = {2, 3, 4}; // global

int main() {
    f<array>(); // print 2
    g<array>(); // print 2
}
```

Class member

```cpp
struct A {
    int x   = 5;
    int y[3] = {4, 2, 3};
};

template<int A::*x>     // pointer to
void h1() {}           // member type

template<int (A::*y)[3]> // pointer to
void h2() {}           // member type

int main() {
    h1<&A::x>();
    h2<&A::y>();
}
```

Function

```cpp
template<int (*)(int, int)> // <-- signature of "f"
int apply1(int a, int b) {
    return g(a, b);
}

int f(int a, int b) {
    return a + b;
}

template<decltype(f)>       // alternative syntax
void apply2(int a, int b) {
    return g(a, b);
}

int main() {
    apply1<f>(2, 3); // return 5
    apply2<f>(2, 3); // return 5
}
```

Compile-Time Utilities

static_assert

C++11 `static_assert` **is used to test a software assertion at** <u>**compile-time**</u>

If the *static assertion* fails, the program does not compile

```cpp
static_assert(2 + 2 == 4, "test1"); // ok, it compiles
static_assert(2 + 2 == 5, "test2"); // compile error
static_assert(sizeof(void*) * 8 == 64, "test3");
// depends on the OS (32/64-bit)
```

```cpp
template<typename T, typename R>
void f() {
    static_assert(sizeof(T) == sizeof(R)); // message not needed in C++17
}

f<int, unsigned>(); // ok, it compiles
// f<int, char>();   // compile error
```

using **keyword (C++11)**

The using keyword introduces an *alias-declaration* or *alias-template*

- using is an enhanced version of typedef with a more readable syntax
- using can be combined with templates, as opposite to typedef
- using is useful to simplify complex template expression
- using allows to introduce new names for partial and full specializations

```cpp
typedef int distance_t; // equal to:

using distance_t = int;
```

```cpp
typedef void (*function)(int, float); // equal to:

using function = void (*)(int, float);
```

Full/Partial specialization alias:

```cpp
template<typename T, int Size>
struct Vector {};                    // see next lecture for further details
                                     // on class template

template<int Size>
using Bitset = Vector<bool, Size>; // partial specialization alias

using IntV4 = Vector<int, 4>;        // full specialization alias
```

Accessing a type within a structure:

```cpp
struct A {
    using type = int;
};
using Alias = A::type;
```

C++11 `decltype` **keyword captures the type of an *entity* or an *expression***

- `decltype` never executes, it is always evaluated at compile-type

```cpp
int       x = 3;
int&      y = x;
const int z = 4;
int       array[2];
void      f(int, float);

decltype(x);          // int
decltype(2 + 3.0);    // double
decltype(y);          // int&
decltype(z);          // const int
decltype(array);      // int[2]
decltype(f(1, 2.0f)); // void

using function = decltype(f);
```

```cpp
bool f(int) { return true; }

struct A {
    int x;
};
int x = 3;
const A a;

decltype(x);    // int
decltype((x));  // int&

decltype(f);    // bool (int)
decltype((f));  // bool (&)(int)

decltype(a.x);  // int
decltype((a.x)); // const int
```

C++11

```
template<typename T, typename R>
decltype(T{} + R{}) add(T x, R y) {
    return x + y;
}

unsigned v1 = add(1, 2u);
double   v2 = add(1.5, 2u);
```

C++14

```
template<typename T, typename R>
auto add(T x, R y) {
    return x + y;
}
```

Type Traits

Introspection

Introspection is the ability to inspect a type and query its properties

Reflection

Reflection is the ability of a computer program to examine, introspect, and modify its own structure and behavior

C++ provides compile-time reflection and introspection capabilities through type traits

Type traits (C++11)

Type traits define a compile-time interface to *query* or *modify* the properties of types

The problem:
```cpp
template<typename T>
T integral_div(T a, T b) {
    return a / b;
}

integral_div(7, 2);      // returns 3 (int)
integral_div(7l, 2l);    // returns 3 (long int)
integral_div(7.0, 3.0);  // !!! a floating-point value is not an integral type
```

Two alternatives: (1) Specialize (2) Type Traits + `static_assert`

If we want to **prevent floating-point/other objects division at compile-time**, a
first solution consists in specialize for all integral types

```cpp
template<typename T>
T integral_div(T a, T b); // declaration (error for other types)

template<>
char integral_div<char>(char a, char b) {   // specialization
    return a / b;
}
template<>
int  integral_div<int>(int a, int b) {      // specialization
    return a / b;
}
...unsigned char
...short
...
```

The best solution is to use **type traits**

```cpp
#include <type_traits>        // <-- std type traits library
template<typename T>
T integral_div(T a, T b) {
    static_assert(std::is_integral<T>::value,
                  "integral_div accepts only integral types");
    return a / b;
}
```

`std::is_integral<T>` is a `struct` with a `static constexpr` boolean field `value`

`value` is <u>true</u> if T is a `bool`, `char`, `short`, `int`, `long`, `long long`, <u>false</u> otherwise

---

C++17 provides utilities to improve the readability of type traits

```
std::is_integral_v<T>;  // std::is_integral<T>::value
```

- `is_integral` checks for an integral type (`bool` , `char` , `unsigned char` , `short` , `int` , `long` , etc.)

- `is_floating_point` checks for a floating-point type (`float` , `double`)

- `is_arithmetic` checks for a integral or floating-point type

- `is_signed` checks for a signed type (`float` , `int` , etc.)

- `is_unsigned` checks for an unsigned type (`unsigned` , `bool` , etc.)

- `is_enum` checks for an enumerator type (`enum` , `enum class`)

- `is_void` checks for (`void`)

- `is_pointer` checks for a pointer (`T*`)

- `is_nullptr` checks for a (`nullptr`) C++14

Entity type queries:

- `is_reference` checks for a reference (`T&`)

- `is_array` checks for an array (`T (&)[N]`)

- `is_function` checks for a function type

Class queries:

- `is_class` checks for a class type (`struct` , `class`)

- `is_abstract` checks for a class with at least one pure virtual function

- `is_polymorphic` checks for a class with at least one virtual function

Type property queries:

- `is_const` checks if a type is `const`

Type relation:

- `is_same<T, R>` checks if `T` and `R` are the same type

- `is_base_of<T, R>` checks if `T` is base of `R`

- `is_convertible<T, R>` checks if `T` can be converted to `R`

Example - `const` Deduction

```cpp
#include <type_traits>
template<typename T>
void f(T x) {  cout << std::is_const_v<T>;  }

template<typename T>
void g(T& x) {  cout << std::is_const_v<T>;  }

template<typename T>
void h(T& x) {
   cout << std::is_const_v<T>;
   x = nullptr; // ok, it compiles for T: (const int)*
}
const int a = 3;
f(a); // print false, "const" drop in pass by-value
g(a); // print true
const int* b = new int;
h(b); // print false!! T: (const int)*
```

Example - Type Relation

```cpp
#include <type_traits>
template<typename T, typename R>
T add(T a, R b) {
    static_assert(std::is_same_v<T, R>, "T and R must have the same type")
    return a + b;
}
add(1, 2);       // ok
// add(1, 2.0); // compile error, "T and R must have the same type"
```

```cpp
#include <type_traits>
struct A {}
struct B : A {}

std::is_base_v<A, B>;          // true
std::is_convertible_v<int, float>; // true
```

Type Manipulation

Type traits allow also to manipulate types by using the `type` field

Example: produce `unsigned` from `int`

```cpp
#include <type_traits>

using U = typename std::make_unsigned<int>::type; // see next lecture to understand
                                                  // why 'typename' is needed here
U y = 5;  // unsigned
```

C++14 provides utilities to improve the readability of type traits

```cpp
std::make_unsigned_t<T>;  // instead of 'typename std::make_unsigned<T>::type'
```

Signed and Unsigned types:

- `make_signed` makes a signed type

- `make_unsigned` makes an unsigned type

Pointers and References:

- `remove_pointer` remove pointer (`T*` $\rightarrow$ `T`)

- `remove_lvalue_reference` remove reference (`T&` $\rightarrow$ `T`)

- `add_pointer` add pointer (`T` $\rightarrow$ `T*`)

- `add_lvalue_reference` add reference (`T` $\rightarrow$ `T&`)

`const` **specifiers:**

- `remove_const` remove `const` (`const T` → `T`)

- `add_const` add `const`

Other type transformation:

- `common_type`<T, R> returns the common type between `T` and `R`

- `conditional`<pred, T, R> returns `T` if `pred` is `true`, `R` otherwise

- `decay`<T> returns the same type as a function parameter passed by-value

Type Manipulation Example

```cpp
#include <type_traits>
template<typename T>
void f(T ptr) {
    using R = std::remove_pointer_t<T>;
    R x = ptr[0]; // char
}

template<typename T>
void g(T x) {
    using R = std::add_const_t<T>;
    R y = 3;
//  y   = 4;    // compile error
}

char a[] = "abc";
f(a); // T: char*
g(3); // T: int
```

std::common_type Example

```cpp
#include <type_traits>

template<typename T, typename R>
std::common_type_t<R, T> // <-- return type
add(T a, R b) {
    return a + b;
}

// we can also use decltype to derive the result type
using result_t = decltype(add(3, 4.0f));
result_t x = add(3, 4.0f);
```

`std::conditional` Example

```cpp
#include <type_traits>

template<typename T, typename R>
auto f(T a, R b) {
    constexpr bool pred = sizeof(T) > sizeof(R);
    using S = std::conditional_t<pred, T, R>;
    return static_cast<S>(a) + static_cast<S>(b);
}

f(   2,  'a'); // return 'int'
f(   2, 2ull); // return 'unsigned long long'
f(2.0f, 2ull); // return 'unsigned long long'
```
